### INTRODUCTION

Studies on the Chalcidoidea fauna of Meghalaya are very limited and the state has not been systematically surveyed for encyrtids, mymarids and aphelinids though they play an important role in natural and applied biological control. Hayat and his co-workers have contributed to the known fauna of Meghalaya (Hayat, 1998; Hayat, 2006; Kazmi and Hayat, 2012; Zeya and Hayat, 1995). We surveyed four districts of Meghalaya in 2013 for Chalcidoidea with particular reference to Encyrtidae, Aphelinidae and Mymaridae and documented several taxa new to the state. The results of our studies are presented in this paper.

### MATERIALS AND METHODS

Extensive surveys were conducted from 31st May to 17th June 2013 at various places in Ri-Bhoi, Jaintia hills, East Khasi hills, and West Khasi hills districts of Meghalaya for collection of Chalcidoidea. Different collection methods (host rearing, net sweep, yellow pan trap and Malaise trap) were used for collection from different ecosystems. Collected parasitoids were processed and curated as per standard protocol (Noyes, 1982) and identified using appropriate keys. Voucher specimens are deposited with ICAR - National Bureau of Agricultural Insect Resources (ICAR-NBAIR), Bangalore, Karnataka, India. Imaging was done using Leica M205A stereo microscope and

composite images were obtained from image stacks using Combine ZP. The images were arranged in plates in Adobe Photoshop Elements 11.

### RESULTS AND DISCUSSION

During the survey, 950 specimens of chalcidoids and other parasitoids were collected. Twenty two species representing 16 genera of mymarids, 30 species representing 28 genera of encyrtids, 10 genera and 8 species of aphelinids and *Orasema initiator* Kerrich of eucharitid are reported as new distribution records for Meghalaya as listed below. Notes on distribution and hosts (wherever known) are provided for all the species. A brief diagnostic account is given only for *Orasema initiator* Kerrich as it has been recorded as a pest of tea by Kerrich (1963).

#### Diagnosis

**Female (Fig. 1):** Head, mesosoma and metasoma dark metallic blue; antennal scape yellowish brown, flagellum yellowish brown; legs yellowish to orange except all coxae, trochanters and femora dark brownish blue, ovipositor reddish brown with a series of distinct serrations; wings hyaline. Fore wing with marginal vein elongate, postmarginal vein short, only slightly longer than stigmal vein. For detailed description, see Kerrich (1963).

**Male (Fig. 2):** Similar to female in general appearance and coloration except hind tibiae slightly more dusky

brown, wings visibly shorter, petiole distinctly longer (more than 2x as long). Antenna similar to female except for the dark brown scape and slightly darker flagellum. Head 1.4x as broad as high. Malar space 0.7x height of eye. Eyes separated by 1.7x their height. Flagellum 1.4x as long as height of head. Fore wing 2x as long as broad. Petiole 5.4x as long as broad, about 2x as long as hind coxa.

**Host:** Recorded as a pest of tea by Kerrich (1963).

Fig. 1. *Orasema initiator*, female.

Fig. 2. *Orasema initiator*, male.

**Comments.** This species is closely related to *O. assectator* in general appearance, but can be distinguished from the latter by the distinctly shorter postmarginal vein, more elongate petiole, and the presence of dorsal and lateral keels on the petiole (Kerrich, 1963). Heraty (1994) has described both sexes of *O. initiator* with illustrations.
