## Response of Seed-Borne Pathogens of Cereal Crops to Azotobacter chroococcum Strains

SUDHIR U. MESHRAM, H.G. GONDANE, S.S. PANDE and S.J.GAIKWAD\* Department of Microbiology, L.I.T. Campus Nagpur University, Nagpur - 440 010

#### ABSTRACT

Studies on cereal seed inoculation with Azotobacter chroococcum (Beijerinck) isolates conclusively showed that selection of suitable isolates of A. chroococcum is essential to derive maximum benefits from seed bacterization. Comparatively, isolates A<sub>5</sub>, M<sub>4</sub> and M<sub>8</sub> proved to be more effective than others in improving the seed germination and suppressing seed - borne fungi of cereal crops. Combined application of pesticides with Azotobacter inoculation increased the grain yield of sorghum with a saving of 40 kg N ha<sup>-1</sup>.

# KEY WORDS : Azotobacter chroococcum, antagonism, seed pathogens, cereal crops

Control of seed-borne diseases of cereal crops by natural means is essential to improve the seed germination as, these seed - borne pathogens are capable of producing most devastating diseases destroying 90% or more of cereal crops. Screening of the isolates of Azotobacter chroococcum (Beijerinck) for their antagonism on agar plates against pathogens isolated from the infested seeds and plants of cereals has already been reported (Meshram et al., 1990). The beneficial effects of A. chroococcum on cereal crops following inoculation of seeds or seedlings has been attributed to multiple action of the antagonist in soil viz., 'N' fixation, suppression of plant pathogens, production of growth promoting substances, effect on other beneficial microorganisms, and mobilization of soil phosphate (Brown, 1974; Mishustin and Naumova, 1962; Shende et al., 1975). The aim of the present study was to test the antagonistic activities of isolates of A. chroococcum against seed-borne fungi of cereals in vitro and subsequently its influence particularly on sorghum in relation to the effect on germination and yield of grains under field condition.

### MATERIALS AND METHODS

A total of 124 A. chroococcum isolates were obtained from the rhizospheres of wheat, maize, sorghum and rice grown in Vidharbha region. These isolates were identified as per the methods adopted while screening of Azotobacter spp. by Apte (1978). In the present study, the isolates of A. chroococcum were selected on the basis of the maximum inhibition zone formed on agar plates against the growth of various pathogens of cereal crops.

The experiment was carried out in Petriplates using maize, wheat, rice and sorghum seeds. Seven-day-old cultures of A. Chroococcum isolates ranging from 30-35 X  $10^8$  cells ml<sup>-1</sup> were prepared in Ashby's liquid medium. Seeds of maize, wheat, rice and sorghum were kept in sterilized Petri-plates containing watersoaked cotton and blotting paper and inoculated with 0.1 ml culture of A. chroococcum. In the control, 0.1 ml sterilized uninoculated broth medium was used as an inoculum. These Petriplates were kept at  $28^\circ$ c and percentage of germination was recorded after 24 h.

Department of Plant Pathology, College of Agriculture, Nagpur - 440 010

The second set of experiments was carried out with seed treatment of 0.1% HgCl<sub>2</sub> solution followed with 3 distilled water washes and an inoculation of 0.1 ml broth culture of *Azotobacter*. In the control, seeds were treated with HgCl<sub>2</sub>, washed and inoculated with 0.1 ml sterilized Ashby's broth.

The effect of various treatments on the germination and plumule formation of wheat, sorghum, maize and rice along with the percentage of pathogen infection was recorded after 48 h with a final observation after 120 h. The pathogens that infected the seeds were identified by Plant Pathology Department, College of Agriculture, Nagpur.

A field plot experiment with sorghum (CvCSH-1) was conducted during the *kharif* season of 1990 with ten treatments, each in triplicate in randomised block design. An individual net plot size of  $0.92 \times 0.92 \text{ m}^2$  was maintained. Soil of the experimental field was sandy loam with a pH of 7.9 and contained 0.021% total N, 0.179% organic carbon and 0.001% available phosphorus. Basal doses of NPK were applied @ 80 Kg N ha<sup>-1</sup> in split form, 50 kg P ha<sup>-1</sup> and 40 Kg K ha<sup>-1</sup>. However, plots inoculated with *Azotobacter* received only 40 kg N ha<sup>-1</sup> as urea in a split application, one half applied at sowing time and the other half as a top dressing 40 days after sowing.

Prior to inoculation and sowing of seeds of sorghum, surface sterilization with 0.1%HgCl<sub>2</sub> (2 min.) followed by washing with water was carried out. As per treatments, seeds were treated with heavy (15-day-old) broth cultures of *Fusarium equiseti* (Corda Saccardo) + *Cladosporium oxysporum* (Berkeley & Curtis) ( $10^7$  to  $10^8$  propagules m1<sup>-1</sup>). The pathogenicity test was done with reference to seed-borne pathogens of sorghum. According to the treatment, *Azotobacter* isolates and pesticide application were done after the pathogen inoculation. Seeds were treated with 10-day-old *Azotobacter* culture prepared in Ashby's liquid medium containing fine mesh powder of charcoal. The density of A. chroococcum isolates ranged from 16-24 x  $10^8$  cells m1<sup>-1</sup>. The Azotobacter M4 & A5 were selected on the basis of constant antagonistic phenomenon shown under laboratory condition. Within 10 days of in cubation, isolates M4 and A 5 fixed N2 7.90 to 8.70 mgN/gm of sucrose consumed respec tively. In case of pesticide treatments, dry seed dressing of Thiram @ 0.25% + Vitava @ 0.1% was done. Other agronomic practices were followed commonly during the vegetative period of the crop.

Seed germination per cent was recorded after 20 days of sowing and no gap filling wa done. The infestation of inoculated pathogens and other microflora of non-ger minated seeds was investigated. At harvest data on grain yield were collected. The statis tical differences in results were compared a 5% level by adopting the technique o 'analysis of variance' (Fisher, 1958).

#### **RESULTS AND DISCUSSION**

Inoculation of Azotobacter isolates sup pressed the growth of pathogens, and en hanced the seed germination in whea depending upon the type of isolates used (Table 1). Isolates A5, M4 and M7 proved to be much better than the other recording 10t per cent germination of the seeds. Azotobac ter inoculation combined with HgC12 treat ment improved the seed germination of ric (Table 1). But seed germination in rice wa lower than in wheat. The per cent of see germination along with their plumule forma tion of maize was comparatively higher with A. chroococcum A5, M4 and M8 isolates. Th Azotobacter isolate R2 in combination 0 HgC1<sub>2</sub> treatment resulted in 100% seed get mination as well as plumule formation in sou ghum. Azotobacter inoculation alone and i combination of HgC12 treatment could con trol the infestation of various seed-born microflora of rice crop as compared to th control (Table 2). However, infection b

Table 1. Effect of Azotobacter and other treatments on the percentage germination (G) and plumule formation (P) of cereals

Aspergillus sp. was higher when compared to other pathogens. Treatment of Azotobacter (As, A<sub>6</sub>) alone and in combination of HgC1<sub>2</sub> and isolates A2, A5, M4, M7, M8 and R2 proved to be highly effective. Infestation was totally absent. Comparatively, the combination of treatments proved much better controlling infestation of various microflora of wheat seeds. Whereas Azotobacter inoculation alone proved less effective as compared to Azotobacter inoculation in combination of HgC1<sub>2</sub> treatment. Infection by Aspergillus sp. was noticed more on wheat seeds. The combined effect of Azotobacter inoculation and HgC1<sub>2</sub> treatment on maize seeds proved much better in respect of all other treatments. Azotobacter inoculation alone, particularly isolate As protected the seeds much better from the infestation of various microflora. Azotobacter seed inoculation alone could not protect sorghum from the infestation by various seed borne pathogens. Whereas the treatment consisting of Azotobacter inoculation + HgC1<sub>2</sub> could suppress the infection effectively. In this combination treatment, the isolates M4 and M8 were found to be most effective.

Antifungal action of A. chroococcum against Aspergillus sp., Penicillium spp., Fusarium spp. and Alternaria spp. have been reported by Mishustin (1966) and Lakshmi Kumari et al. (1972). According to Linchevskaya and Kaliberad (1958), late blight of potato incidence could be minimized or reduced by applying Azotobacter.

A number of workers reported that seed inoculation with *Azotobacter* inhibited or prevented the occurrence of viral, fungal and bacterial diseases of some agricultural crops (Dorosinskii, 1962; Khudyakov and Marschunova, 1966). The success of the inoculation varies with temperature, and also

Table 2. Effect of Azotobacter isolates and other treatments on various micro-flora of cereals seeds

The fungus is yet to be identified \*

NOTE : Rhizopus was found growing vigorously in case of Azotobactor alone treatments.

06

Asp. = Aspergillus sp.; Pyt. = Pythium sp.; Peni. = Penicillium sp.; Fus. = Fusarium sp. Hel. = Helminthosporium sp.;

Al = Alternaria sp.: Cul. = Culvularia sp.: Pho. = Phoma sp.; Cla. = Cladosporium sp

depends on the selection of appropriate isolates (Meshram and Jager, 1983). Inoculation with an isolate of Verticillium biguttatum in combination with isolates of A. chroococcum effectively protected sprouts, stems and stolons against the infestation with R.solani (Meshram, 1984); the yield also increased significantly over the control.

Results of the field trial conducted on sorghum revealed that the efficacy of Azotobacter isolates varied under the field condition also (Table 3). This indicates that screening of A. chroococcum strains in laboratory as well as field condition is essential prior to recommendation of package of treatment. The application of pesticides alone and combined with Azotobacter and seed-borne inoculated pathogens gave the highest germination rate. However, the seed bacterization of Azotobacter isolates alone proved to be statistically non- significant though higher per cent germination was observed compared to control. Inoculation of these isolates combined with seed-borne inoculated pathogens proved to be less effective. This might be due to the heavy inoculum of pathogens artificially in addition to natural presence of seed-borne microflora as recorded in Table 2 with the same variety of seeds. Further, the per cent of seed germination recorded in the treatments of inoculated seed- borne pathogens was found much lower. Most of the traceable non-germinated seeds were found totally deterioated and infected with *Fusarium*, *Cladosporium and Culvularia* spp.

The application of pesticides proved to be very effective when combined with Azotobacter inoculation, the increase of grain yield was obtained with saving of 40 kg N ha<sup>-1</sup>. Of course, the significant effect of these treatments on yield is due to the high rate of germination of seeds. Besides, the gradual release of N fixed by Azotobacter may have resulted in higher efficiency with low level of nitrogenous fertilizers i.e. 40 kg N ha<sup>-1</sup> when compared with high level 80 kg N ha<sup>-1</sup>. No response to Azotobacter inoculation combined with pathogens was obtained. Obviously, this is due to introduction of pathogenic inoculum with seed treatment. Inoculum density is generally known to be directly proportional to disease severity (Baker, 1968). To add this, an inoculation of Azotobacter M4 alone proved to be much beneficial with a grain yield of 26.20 Q/ha.

The effect of pesticides such as thiram, and vitavax on *Azotobacter* inoculant needs to be studied. The favourable effect of *Azotobacter* inoculation obtained is attributed due to multiple action. However, prior to use of

| Treatment                               | Seed Germination<br>(%) | Grain yield<br>(Q ha <sup>-1</sup> ) |  |  |
|---|-------------------------|--------------------------------------|--|--|
| Control                                 | 53.79                   | 21,52                                |  |  |
| Pathogens alone                         | 43.71                   | 18.54                                |  |  |
